ABSTRACT

Background: Acute radiation proctitis is a common complication of pelvic radiation and management of acute radiation proctitis is under evaluation. The beneficial effects of ozonated olive oil (OzOO) have already been shown in the treatment of chronic wounds. Thus, this study was designed to evaluate the therapeutic effects of topical OzOO on acute radiation proctitis.

Aims: To evaluate the therapeutic effects of topical OzOO on acute radiation proctitis.

Study Design: Animal experimentation.

Methods: Rats were divided into three groups: control; irradiation+saline (1 mL); and irradiation +OzOO (1 mL). A single fraction of 17.5 Gy was delivered to each rat. The OzOO was administered rectally each day after irradiation. Each rat was observed daily for signs of proctitis. Irradiated rats were euthanised on days 5 and 10. The mucosal changes were evaluated macroscopically and pathologically.

Results: According to the clinical findings, five rats in the irradiation+saline group showed Grade 4 symptoms on the 10th day. Macroscopic finding scores on the 10th day in the irradiation+saline and irradiation+OzOO groups were statistically significantly different. On pathological examination, radiation-induced mucosal damage was the most prominent 10 days after irradiation in saline-treated rats. On the 10th day, the irradiation+OzOO group showed mild inflammation and slight crypt change, which corresponded to Grade 1 pathological findings.

Conclusion: OzOO attenuates macroscopic and pathological findings of acute radiation proctitis in rats.

Key Words: Ozonated olive oil, radiation proctitis

Introduction

Radiotherapy has paramount importance in the management of pelvic organ malignancies. However, pelvic location of the rectum and its anatomic relationship with other organs increase the risk of secondary radiation injury with resulting proctitis. Radiation injury may occur in an acute or chronic form. Acute radiation proctitis (ARP) is observed in 50–75% of patients, either during radiotherapy or up to 6 weeks after completion of radiotherapy, and symptoms of radiation injury decrease in 2–6 months. Symptoms of ARP are diarrhoea, intermittent bleeding, nausea, abdominal pain, mucous discharge, constipation, and various urinary symptoms (1). Inflammation, edema, epithelial degeneration, ulceration, crypt disintegration, mucosal edema, absent mitosis, and crypt abscesses are the histopathological changes found in ARP (2, 3).

There have been numerous therapies with the aim to prevent or reduce the symptoms of radiation proctitis including medical therapy, such as corticosteroids (4), sucralfate (5, 6), metronidazole (7), and formalin (8, 9), endoscopic treatment, such as various lasers, including argon plasma coagulation (10), yttrium-aluminium-garnet laser (11), and treatment with hyperbaric oxygen (12, 13). However, suggested therapies of

radiation proctitis have not proven to be effective, and their beneficial effects are limited. Therefore, the search for a more effective therapy continues.

Ozone (O_3) is well known as one of the best bactericidal, antiviral, and antifungal agents and is profitably and practically employed as Ozonated olive oil (OzOO) with well-defined peroxide contents. OzOO has been reported to be used topically for the treatment of war wounds, anaerobic infections, herpetic infections (HHV I and II), trophic ulcers and burns, cellulitis, abscesses, anal fissures, decubitus ulcers, fistulae, fungal diseases, furunculosis, gingivitis, and vulvovaginitis (14). It has been hypothesised that the mechanism of action of ozonated oil on wound healing may be connected in part to its antimicrobial effect but also to its ability to promote the generation of growth factors, activate local antioxidant mechanisms, and promote tissue repair (15). Therefore, the topical application of OzOO may produce beneficial effects in the management of ARP. In this study, we aimed to assess the efficacy of topical OzOO in the management of ARP.

Material and Methods

The experimental protocols were conducted with the approval of the Animal Research Committee at Bülent Ecevit Uni-

This study was presented at the 14th National Colon and Rectal Surgery Congress, 15–19 May 2013, Antalya, Turkey

versity, Zonguldak. All animals were maintained in accordance with the recommendations of the National Institutes of Health Guidelines for the Care and Use of Laboratory Animals.

Animals

Thirty-five female Wistar albino rats weighing 200–230 g at the age of 6 weeks were obtained from the Institute for Experimental Medicine, Bülent Ecevit University. All animals were acclimatised for 7 days prior to the experiments in the laboratory of the mentioned institute. Rats were housed in cages and were allowed free access to standard rat chow and water before and after the experiments. The animal rooms were windowless, with temperature ($22\pm2^\circ\text{C}$) and lighting controls. The animals were fasted overnight before the experiments but were given free access to water.

Rats were randomly divided into three groups: 14 animals in the irradiation (IR)+saline group; 14 animals in the IR+OzOO group; and seven animals in the control group. Both the saline and OzOO groups were irradiated in the pelvic area with 17.5 Gy as a single dose. For the IR+OzOO group, 1 mL OzOO was administered intrarectally twice a day from the day of IR until the day of euthanasia. For rats in the IR+saline group, the same protocol was performed with saline. The rats in the control group received no saline or OzOO and underwent sham IR.

Pelvic irradiation

Simulation of the IR was performed by computed tomography simulation. Each rat was anaesthetised using 5 mg/kg xylazine (Rompun, Bayer Türk, İstanbul, Turkey) and 30 mg/kg ketamine hydrochloride (Ketalar, Pfizer, İstanbul, Turkey) delivered intramuscularly prior to IR. Then, three to four rats at a time were restrained and taped by the tail and legs on an acryl plate in a supine position. The rats were covered for a 3 cm \times 4 cm area of the lower pelvis containing a 2-cm length of the rectum in the middle of the field. IR was delivered with 6 MV linear accelerator with the SAD technique. The irradiated area was verified by portal imaging. A bolus material was placed on the irradiated area. A dose of 17.5 Gy in a single fraction was delivered to each rat. A dose similar to this one has been shown to be optimal for clinically relevant proctitis using the same rat radiation model (16).

Treatment with ozonated olive oil

OzOO was generated by an ozone generator, which allowed control of the gas flow rate and ozone concentration in real time using a built-in ultraviolet (UV) spectrometer and was kept in a dark bottle at 4°C until used, within 24 h. OzOO was produced at a concentration of approximately 14 μg of ozone/mL of olive oil. The OzOO, which was prepared in a 1 mL volume at body temperature, was given twice a day beginning on the first day after IR until the euthanasia day. The OzOO was applied with a soft feeding tube and then the anus was temporarily closed with a digital compress for 5 minutes.

Evaluation of rectal damage

Each rat was observed daily for signs of proctitis, such as diarrhoea and rectal bleeding, after IR. The clinical findings

were scored as follows: 0, no symptoms; 2, diarrhoea; and 4, gross bleeding. Seven rats were euthanised on each of the 5th and 10th days after IR for macroscopic and histological evaluation. Euthanasia was performed by cardiac exsanguination under a surgical plane of 100 mg/kg ketamine hydrochloride and 20 mg/kg xylazine anaesthesia. A midline laparotomy incision was made. The small bowel was moved aside to reveal the distal large bowel. The pelvic symphysis was cut and elevated to facilitate access to the distal rectum and anus. The 2 cm of distal rectum adjacent to the anal region was excised. The rectums were macroscopically evaluated and scored as follows (17): 0=normal mucosa; 1=edema, mild hyperaemia, or decreased vascularity; 2=diffuse hyperaemia, multiple punctuated areas of haemorrhage, or confluent areas of haemorrhage; 3=presence of erosions or frank haemorrhage; and 4=ulcers. For histological evaluation, a portion of the specimen was excised, fixed in 10% buffered formalin solution, embedded in paraffin, and cut into 5- μm sections. The sections were stained with haematoxylin-eosin (HE) and examined under a light microscope by a blinded pathologist for histopathological changes. Each specimen was graded as follows (16): Grade 0, normal or minor alterations that cannot be correlated to radiation with certainty; Grade 1, slight radiation damage (mild inflammation and/or slight crypt change); Grade 2, mild damage (more significant inflammation and/or slight crypt change); Grade 3, moderate damage (must have prominent loss of epithelium and/or variable degree of inflammation); and Grade 4, severe damage (ulcer, necrosis).

Statistical analysis

Statistical analyses were performed with SPSS 18.0 software (SPSS Inc., Chicago, IL, USA). Kruskal-Wallis test was used to determine the differences between groups. Bonferroni-adjusted Mann-Whitney U test was used for post-hoc test after the Kruskal-Wallis test (p values <0.005 were considered statistically significant).

Results

No mortality was observed in the groups. Differences in the mean body weight among the groups were found to be statistically significant ($p<0.001$). The mean body weight on the 10th day after IR was found to be significantly lower than that in the control group (223.6 ± 3.5 g); 204 ± 3.1 g and 214.9 ± 4.3 g, control, IR+saline, and IR+OzOO groups, respectively ($p=0.001$). However, the mean body weight on the 5th day after IR was 215.4 ± 4.9 g and 216 ± 3.2 g in the IR+saline and IR+OzOO groups, respectively, with no significant difference.

The results of the clinical findings are listed in Table 1. Only two rats from the IR+OzOO group were apparently healthy on the 5th day, and their clinical finding scores were Grade 0. Grade 2 symptoms were noted in six rats on the 5th day in the IR+saline group, five rats on the 5th day in the IR+OzOO group, and five rats on the 10th day in the IR+OzOO group. On the 10th day, the IR+saline group had a greater frequency of Grade 4 than did the other groups. Although on the 10th day the IR+saline group had a higher clinical score than the

IR+saline group on the 5th day, the difference was not statistically significant (Table 2).

The scores of gross mucosal change are listed in Table 3. Macroscopic changes were maximal in the IR+saline group on the 10th day. The numbers of rats showing Grade 1 and Grade 2 macroscopic findings were similar on the 5th day in the IR+saline and IR+OzOO groups. Treatment with OzOO

for 10 days following IR attenuated macroscopic findings in the IR+OzOO group compared with the IR+saline group, 3.71 (± 0.48) and 2.57 (± 0.78), respectively. However, the difference between groups did not reach statistical significance (Table 2).

The most significant histopathological changes were observed in the IR+saline group on the 10th day after IR (Table 4). Severe changes were characterised by the loss of epithe-

lum through the muscularis mucosa and mucosal ulceration (Figure 1). Comparing the histological changes in the 5th and 10th day specimens, the most prominent changes in the 5th day specimens were moderate inflammation and slight crypt change (Figure 1). Although not found to be statistically significant, the IR+saline group had milder histopathological changes on the 5th day than the IR+saline group did on the 10th day. OzOO attenuated pathological findings of ARP. Five rats in the IR+OzOO group on the 5th day and four rats in the IR+OzOO group on the 10th day showed Grade 1 histopathological changes (Figure 1). Pathological finding score was decreased on the 5th day in the IR+OzOO group (2.29 ± 0.48) compared with that on the 5th day in the IR+saline group (3.29 ± 0.48 , Table 2). However, no significant difference was found regarding the pathological finding score between the groups on the 5th day. OzOO treatment for 10 days after IR significantly reduced inflammation and crypt changes, and the difference between the IR+saline and IR+OzOO groups on the 10th day was statistically significant ($p=0.002$) (Table 2).

Discussion

ARP is characterised by an inflammatory process involving only the superficial mucosa (18) that develops immediately after the initiation of therapy or up to 3 months after the onset of therapy (19). Symptoms including diarrhoea, nausea, cramps, tenesmus, urgency, mucus discharge, and minor bleeding may occur in up to 20% of patients, leading to an interruption in treatment (20). Much research has been con-

ducted to define best therapy for prevention or reduction of symptoms of ARP.

Radiation therapy results in oxidative stress and it has been demonstrated that free oxygen radicals have a crucial role in radiation-induced normal tissue toxicity and in inflammation. The increase in antioxidant enzyme levels may prevent damage of IR to normal tissues and reduce the inflammation (6). Ozone therapy has beneficial effects in various diseases, such as caustic oesophageal burn, diabetic foot, and radiation-induced cystitis (21-23). It can be applied by topical, rectal, peritoneal (animal studies), or oral (ozonised water or oil) routes. The term 'ozone oxidative preconditioning' refers to the repeated application of ozone in order to increase antioxidant enzymes and keep the organism alert, as in vaccination. Ozone oxidative preconditioning provides protection against the cellular damage caused by free radicals (24). In our previous study, we also investigated the effects of ozone oxidative preconditioning in the prevention of acute radiation toxicity in rat liver and intestine. Ozone was found to be effective for the prevention of radiation-induced ileal injury (25). However, data on the use of ozone or ozonated oils in radiation proctitis are limited. Recently, Clavo et al. (26) reported the beneficial effects of ozone therapy on refractory haemorrhagic radiation proctitis. In the study, 17 patients received an ozone gas mixture via rectal insufflations and topical application of ozonised oil, and were followed up for a median of 40 months (3–56 months). Clavo et al. (26) concluded that ozone treatment improved the clinical symptoms of haemorrhagic radiation proctitis. However, this is the only study published in the English-

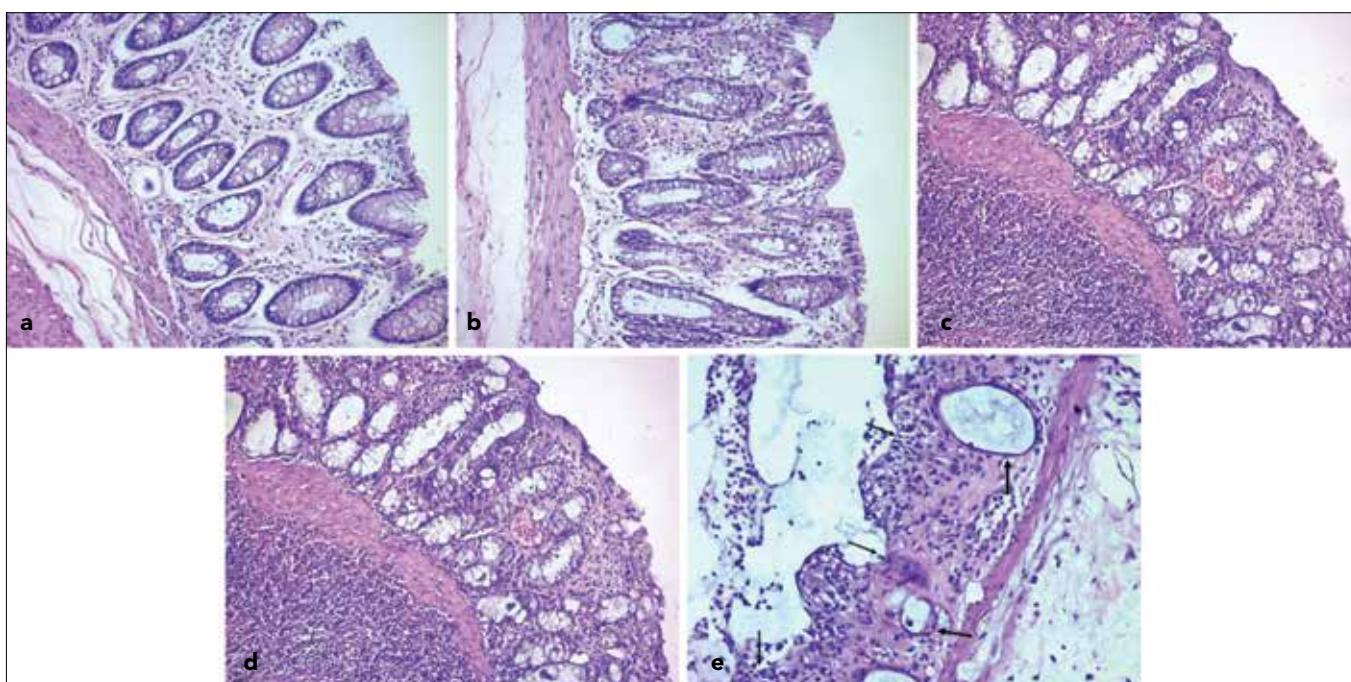

Figure 1. a-e. Normal rectal mucosa (Grade 0) in the control group (H&E, x200) (a). Grade 1 histological change: mild inflammation and slight crypt change in ozone-treated groups on the 5th day (H&E, x200) (b). Grade 2 histological change: moderate inflammation and slight crypt change in ozone-treated groups on the 10th day (H&E, x200) (c). Grade 3 histological change: prominent loss of epithelium (arrow) and severe inflammation in radiation-treated groups on the 5th day (H&E, x200) (d). Grade 4 histological change: severe crypt damage (thick arrows), inflammation, and ulceration (thin arrows) in radiation-treated groups on the 10th day (H&E, x200) (e)

language literature, and to date, no studies have reported the effects of OzOO on histopathological findings of ARP in animals or in humans.

In the present study, the sequential changes following IR were observed in rats. In the clinical findings, results that were greater than Grade 2 findings were found in saline-treated groups on the 10th day following IR, whereas only one rat showed Grade 4 findings on the 5th day in the IR+saline group. Although fewer Grade 4 clinical findings, which included diarrhoea and melaena, were observed on the 10th day in the IR+OzOO group, no significant differences were found between the groups on the 10th day in terms of clinical findings.

Grossly, ARP is an inflammatory process of the rectal mucosa that appears oedematous, beefy red, and may have ulceration or sloughing. The present study evaluated mucosal changes on the 5th and 10th days after IR. Apparent mucosal changes were observed on the 10th day in the IR+saline group. The macroscopic findings were consistent with those from previous reports. Kang et al. (16) reported that erosion of the surface epithelium, which started on the 6th day after IR, progressed to multifocal ulceration with severe inflammation until the 10th day after IR. Macroscopic finding score on the 10th day after IR was 3.71, which meant that most specimens revealed Grade 3 findings, and intrarectal application of OzOO for 10 days improved macroscopic mucosal changes of ARP, but the difference was not significant.

Mucosal damage in the rectum was evaluated pathologically, and the pathological findings were consistent with those from previous reports (3, 16, 17). The pathological differences on the 10th day in the IR+saline group were more obvious, and mucosal ulceration and crypt damage were the predominant characteristics of acute radiation toxicity. OzOO-treated groups had statistically significantly lower scores.

In the present study, the rectum was examined clinically, macroscopically, and pathologically, and the rats that received OzOO tended to show milder rectal damage than the other groups for all criteria of the study. However, the differences did not reach statistical significance in terms of clinical and macroscopic finding scores. On the 10th day, the IR+saline group had a significantly higher pathological finding score than the IR+OzOO group. Moreover, 10-day OzOO treatment appeared to be more effective than 5-day OzOO treatment after IR in the study. Thus, OzOO was confirmed to have beneficial effects on ARP. Ozone was chosen for its demonstrated benefits in radiation-induced cystitis (23), refractory haemorrhagic radiation proctitis (26), and ileal injury (25). Calvo et al. (23) reported that ozonated bi-distilled water could be administered intravesicularly to prevent haematuria caused by radiation-induced cystitis. More recently, the authors also reported their experience with ozone therapy in the treatment of refractory haemorrhagic radiation proctitis. Oxygen radicals in radiation-induced gastrointestinal disorders have been demonstrated, and in our previous study, intraperitoneally administered ozone was shown to protect against radiation-induced mucosal injury of the small bowel (25). The radioprotection observed with ozone is attributed to an increase in the endogenous antioxidant defence enzymes and the inhibition of lipid peroxidation.

Some authors have investigated various antioxidant agents in the prevention of acute radiation toxicity. In a study by Doi et al. (27), the use of intrarectal polaprezinc significantly attenuated ARP in rats. Similarly, Yoon et al. (28) found that oral high-dose triphala treatment improved radiation-induced acute intestinal mucosal damage in rats. Moreover, it has been generally accepted that IR damages endothelial cells in the microvessels and causes hypoxaemia (29). It is possible that the effect of ozone reduces the presence of phagocytic cells, thereby reducing the oxidative burst, increasing the oxygen tension, and ameliorating the radiation-induced mucosal damage. In the experiments on full-thickness dermal wound treated with ozonated oils (30, 31), a rise in wound healing rate was reported. Those reports suggested that increased oxygen tension at the wound site increased the formation of granulation tissue, accelerated wound closure, and ameliorated impaired dermal wound healing. Although those reports are not related to radiation protection or mucosa, we can infer that a similar mechanism might be involved from the standpoint of the recovery or re-epithelialisation of damaged tissue. Further studies are required to clarify the mechanism underlying the beneficial effect of OzOO on ARP.

In the literature, the effects of OzOO therapy on radiation proctitis are based on a limited number of scientific studies, often involving small numbers of patients with variable periods of follow-up, and considering only clinical and macroscopic findings. Although we used an animal model of radiation proctitis, we were able to evaluate the effects of OzOO in terms of clinical, macroscopic, and histopathological findings. We conclude that in the treatment of ARP, OzOO given rectally for 10 days reduced rectal mucosal damage, as shown by macroscopic and histopathological findings in rats. However, more research is needed to confirm the beneficial effects of OzOO in radiation-induced proctitis. In addition, clinical trials should be conducted to determine whether OzOO could reduce the severity and frequency of early complications of IR.

Ethics Committee Approval: Ethical approval was received from the Animal Research Committee of Bülent Ecevit University in May 5th, 2013 (2012-23-30/05).
